Prof. Dr. Sonja Utz
Everyday Media Lab
Leibniz-Institut für Wissensmedien (IWM)
Schleichstraße 6, 72076 Tübingen

24 September 2026

Application: Researcher / PhD position, Everyday Media Lab, Ref. 1014-2026

Dear Professor Utz,

I want to study why people believe what AI systems tell them, because I believed what mine told me. For seven years I have worked for more than five companies and over 300 freelance clients, mostly collecting and analysing online data, and a growing share of that work ends in AI-generated figures that readers cannot easily check. Checking them is part of my work, yet the precise figures of my own system persuaded me until I audited what they were scored against. One anecdote proves nothing, but your study with Anderl and colleagues (2024) describes a comparable effect of another cue: people judged the same information more credible, and caught fewer of its errors, when a conversational agent presented it than when it appeared as static text. I hold an MSc in Data Analytics (Distinction) from the University of Portsmouth and a BSc in Computer Science from FAST-NUCES, and am a Data Engineer at M+C Saatchi Fluency and founder and CTO of ArtemisAI. I am applying for this position in the Everyday Media Lab to test whether numeric precision is a similar cue for readers who did not build the system.

At Dubizzle Labs (Senior Data Engineer, 2022 to 2024) I led three engineers collecting text in English, Arabic, Urdu and Hindi across 15 countries. With web scraping and the data warehouse I redesigned, I analysed e-commerce and real estate stores and online discussions to build competitor-analysis dashboards that predicted revenue and showed what customers said. There I first met a measurement problem: people wrote differently on forums and on social platforms, so anything measured from their words depended on where it was collected. My Chevening Scholarship (2024/25) rested on a simple argument: public decisions deserve better evidence about what people think. More of that evidence now comes from AI systems, so it is only as good as a reader's ability to tell when the system is wrong. I took that argument to the University of Portsmouth (MSc awarded December 2025; credit-weighted average 70.5, dissertation mark 78).

My dissertation was an ethics-approved study of about 279,000 posts on UK economic policy from four platforms (X, Reddit, YouTube and Quora), with a fine-tuned BERT classifier (macro-F1 0.878) tested against BiLSTM and lexicon baselines, and a 200-post human-coded validation set (Cohen's kappa about 0.78). The same policy event looked structurally different on each platform. With my supervisor, Dr Ella Haig, I turned that finding into a methods manuscript that treats each platform as a survey mode and adapts measurement invariance and score linking to machine-labelled sentiment. In a 500-replication simulation, a naively pooled index misstates a known event shift by roughly an eighth and gives the wrong sign on nearly a quarter of days, yet it would reach a reader as one precise figure. Writing it up, I found that my own 0.878 had been scored against lexicon-seeded labels rather than the human coders, and the manuscript says so.

At Fluency, where I have worked since December 2024, the core of the work is the same: we analyse online data. I have supported social listening pipelines for UK Government departments and Nike, built the ETL that cleans, translates and tags Amazon's social data, and run a self-repairing crawler fleet that gathers owner-forum discussion for Ford. On the analysis side, where I can share methods but not findings, I classified accounts for a US women's soccer project to separate fans from clubs, outlets and journalists, built a theme codebook from BERTopic topics I merged by hand, and LLM-tagged every post after a pilot I checked by hand and re-ran to see where the model wavered. For Abbott I coded, in LLM-assisted stages, about 170,000 multilingual posts and reviews from 12 platforms for emotions and need states; for Reckitt I set product reviews against search queries on one needs codebook. On a CFMOTO launch report, when the client questioned our method, we audited each brand's mix of news and consumer posts, set a minimum consumer base, re-ran the results on narrower subsets and compared two tagging runs, and reported as directional anything the checks did not support. Treating an LLM coder as an instrument to be tested before its output is believed is, I think, the right preparation for studying when people believe AI output.

ArtemisAI moved the problem from whether a figure is valid to why its readers believe it. It is running in production ahead of our December launch, and each feature turns a model output into advice that a small business owner would act on without being able to check it: flop detection, which warns when a page is at risk of a weak post; crisis detection, which raises alerts from toxicity scores when a comment storm starts; and a collaboration feature that applies network theory to a graph of page

affinity to suggest whom to team up with. Underneath are NLP and OCR pipelines: six fine-tuned encoder classifiers (XLM-R, DistilBERT, DeBERTa-v3, Detoxify) code sentiment, emotion, toxicity, topic, language and intent across over three million comments, alongside OCR, Whisper transcription and a CLIP-based fusion classifier for images and video. To improve the platform we drew on the research literature as well as code: Grimmer, Roberts and Stewart's *Text as Data* gave us rules we are now applying to each feature, such as testing on later data held back until the end; flop detection draws on published popularity-prediction studies; and we studied the ranking code X released as open source.

The figure that persuaded me was the platform's headline average accuracy, which rose from 64.7 to 85.8 per cent over five versions. The first three versions were scored against a test set of 97 human-labelled posts and the last two against Claude's labels, so part of the rise was agreement with another model, not with people. We had labelled about 500 posts and comments by hand and checked Claude's and DeepSeek's labels against them before the classifiers learned from two labelling tiers, Claude (about 6,000 posts) and DeepSeek (about 12,000 more). Toxicity, on which the crisis alerts rest, showed a second problem: the two tiers used incompatible taxonomies and so agreed on none of their labels, while the toxicity model reported 96.7 per cent average confidence, a measure of certainty rather than correctness.

Your paper with Goyanes and Gil de Zúñiga (2026) describes a cue route to trust in AI news through the AI heuristic, alongside an action route through seeing AI as a social entity. Observers also read a precise figure as a sign that the speaker is confident (Jerez-Fernandez, Angulo and Oppenheimer, 2014). People already overestimate how accurate LLM answers are (Steyvers et al., 2025), and a first-person hedge such as "I'm not sure" reduces reliance on them (Kim et al., 2024). My question is whether numeric precision acts as such a cue: whether a precise confidence figure raises credibility judgements independently of accuracy, and makes errors harder to detect, more than the same confidence stated in words.

Study 1 would be a preregistered online experiment extending the accurate versus partially inaccurate paradigm of Anderl et al. (2024), crossing how confidence is stated (verbally or as a precise figure, at matched levels, against a no-confidence control) with whether the content is accurate, measuring perceived credibility and error detection. The stimuli would be LLM summaries of real social media discussion, coded against human judgement so that every statement has a known accuracy, which lets the study use errors that real systems make rather than only planted ones. Study 2 would turn to incidental learning: participants meet the same summaries in a simulated professional feed, and an unannounced later test asks what they remember people said, including the wrong figures. Anderl, Gaiser and Utz (2026) found that work-related reading and posting predicted informational benefits at the same time point but not later, suggesting predominantly short-term benefits; Study 2 asks what persists when the information comes from an AI. I would reshape both designs with you.

The answers would matter for any AI-generated summary of public opinion that professionals read at work, not only for my own product. In planning ArtemisAI's flop warnings we argued for showing owners bands rather than single scores, but I do not know whether that helps readers catch errors or only changes how sure they feel. That is an empirical question about credibility, and it belongs in a lab like yours rather than on a product roadmap. The PhD would give my work what it has lacked, tests with people rather than only against labels, and its answers would inform how systems like mine present their output. In return, I have built the dashboards whose precise figures I now want to test, and I know how they are computed and where they drift. I can generate stimuli from real LLM output, pretest them with the codebooks and human-coded checks I already write, build the simulated feed for Study 2 in Python, and adapt the known-ground-truth simulation from the manuscript to power analysis.

My master's is in data analytics rather than psychology or communication science. My empirical work is quantitative but observational: I have not yet run an experiment with human participants, so I would draft and preregister Study 1 in my first months, within the lab's practice, and learn the mixed-effects analysis such designs need. I have no publications; the manuscript with Dr Haig is complete but not yet submitted. I do not speak German yet and would begin learning it on arrival.

I would accept the 75 per cent contract and relocate to Tübingen, and if my profile fits the agentic science position (1013-2026) better, I would be glad to be considered for it too. My CV, certificates and transcripts follow in this file. Thank you for considering my application. I would welcome the chance to discuss the fit with you.

Yours sincerely,

Asad Ikram

PROFILE

Over seven years I have worked for 5+ companies and 300+ freelance clients, mostly collecting and analysing online data. At Dubizzle Labs, leading a team that collected text in four languages across 15 countries, I saw that people write differently on forums and on social platforms, yet their text was treated as comparable. As a Chevening Scholar I took that problem to the University of Portsmouth, into an MSc dissertation and a methods manuscript with Dr Ella Haig, then into client analysis at M+C Saatchi Fluency and into ArtemisAI, the company I founded, where I found my own system's accuracy figure rising partly because its reference had moved. I now want to study when people believe the numbers AI systems produce, which would also shape how ArtemisAI shows confidence.

Fit with the Everyday Media Lab	Validating automated coding against human coders is how I would build stimuli of known accuracy and manipulation checks. McNemar tests, bootstrap intervals and simulation with known ground truth carry over to experimental data, and my Python pipelines could build a simulated professional feed for studying incidental learning.
Research interests	Credibility judgements of AI-generated information, especially when a precise confidence figure has no relation to correctness; incidental learning and informational benefits from social media and communicative AI at work; validity of automated text coding across platforms, models and time.

ANALYSIS METHODS

Content analysis	Automated content analysis validated against human coding; codebook design, piloting and revision; sentiment, emotion (NRC lexicon; a 24-emotion multi-label taxonomy), need-state, toxicity, topic and intent coding; topic modelling (BERTopic) to find candidate themes; LLM-assisted annotation checked by hand; multilingual text translated before coding. Fine-tuned encoder classifiers (BERT, XLM-R, DistilBERT, DeBERTa-v3).
Statistics	Inter-coder reliability (Cohen's κ); agreement versus criterion validity; McNemar tests, bootstrap confidence intervals, chi-square tests; probability calibration; simulation with known ground truth; checks of coverage, denominators and whether groups can be pooled; cross-market comparison and indexing; minimum-base and small-cell rules; sensitivity analyses.
Measurement	Generalizability theory, measurement invariance, differential item functioning and score linking, specified in a protocol and tested by simulation; not yet fitted to collected data.
Research practice	Ethics approval and GDPR-compliant handling of public text; analysis anchors fixed in advance, before any counts were computed; documented, reproducible analysis pipelines.
Software	Python, PyTorch, SQL, PySpark; R (working knowledge). Data access through official APIs and licensed feeds (Meta Graph, Reddit, YouTube, Brandwatch, Sprinklr); AWS, Airflow, Docker.

EDUCATION

2024 - 2025 awarded Dec 2025	MSc Data Analytics, Distinction. University of Portsmouth, United Kingdom. Credit-weighted average 70.5/100 (Distinction threshold 70). Master's project 78/100, supervised by Dr Ella Haig. Modules included Intelligent Data and Text Analytics, Big Data and Machine Learning, and Explainable AI. 180 UK credits (conventionally 90 ECTS), taught and assessed in English.
2017 - 2021 awarded Jan 2022	BSc Computer Science. National University of Computer and Emerging Sciences (FAST-NUCES), Pakistan. Four years full time, 130 credit hours completed. CGPA 2.75 on a 0.00 to 4.00 scale.

RESEARCH

2025 Master's project	Cross-Platform Sentiment Analysis of Public Reaction to UK Economic Policies. Finding. The same policy event produced different sentiment and emotion profiles on different platforms, so a pooled index assumed, without testing, that the classifier measures the same construct everywhere. Study design. Ethics-approved quantitative study (Portsmouth TETHIC-2025-111094) of about 279,000 public posts and comments on UK economic policy from X/Twitter, Reddit, YouTube and Quora, collected through official APIs and licensed feeds under GDPR-compliant procedures. Human-annotated validation set of 200 posts balanced across platforms (reported inter-annotator agreement Cohen's $\kappa \approx 0.78$). Classification and testing. Fine-tuned BERT classifier compared with BiLSTM by McNemar test ($p < 0.001$) and bootstrap intervals, alongside logistic regression and VADER baselines, with probability calibration. Chi-square tests of sentiment by policy topic; NRC emotion analysis linking anger and fear to negative sentiment in policy discussion. Correction. Re-auditing for the manuscript, I found the headline macro-F1 of 0.878 was agreement with the lexicon-seeded training labels, not with the human set. The manuscript says so and specifies a larger stratified human criterion with a second annotator.
2026 manuscript	Ikram, A. and Haig, E. "Is the Platform Part of the Measurement? A Protocol and Simulation Study for Cross-Platform Equivalence of Machine-Labelled Policy Sentiment." Complete; not published and not submitted. Treats each social platform as a survey mode and asks whether a classifier measures the same construct on each: a generalizability study against a human criterion, invariance and differential item functioning with platform as the grouping facet, and score linking.

- 500-replication simulation with known ground truth: an index that pools platform scores at face value misstates a known event shift by roughly an eighth and reports the wrong sign of aggregate sentiment on nearly a quarter of days; the measurement-adjusted index gets the sign wrong on about one day in sixty. No peer-reviewed publications to date.

EXPERIENCE

Feb 2025 - present

- Founder and Chief Technology Officer**, ArtemisAI Ltd (trading as ViralData), United Kingdom (remote). Social media analytics for small businesses, running in production ahead of a December 2026 launch.
- **Agreement is not validity.** The two labelling tiers agree on 82.9% of sentiment, 74.4% of emotion and 0.0% of toxicity labels (a taxonomy mismatch), while the toxicity model reports 96.7% average confidence: a precise, confident number with no criterion behind it.
 - **A moving reference.** Reported average accuracy rose from 64.7 (v1) to 85.8 (v5), but v1 to v3 were scored against the human holdout and v4 onward against Claude's labels, so part of the gain is the reference moving rather than the model improving.
 - **Products.** Flop detection (warns when a page risks an underperforming post), crisis detection from toxicity scores, best posting times, post drafting, and a collaboration feature built on network theory (a networkx affinity graph of pages).
 - **Models.** Six fine-tuned encoder classifiers code 111,000+ posts and 3.39 million comments from 30+ public pages (Meta Graph API): XLM-R (sentiment), DistilBERT (emotion), DeBERTa-v3 (topic, intent), Detoxify (toxicity) and a language classifier. They learn from a tiered labelling chain via APIs: we hand-labelled about 500 posts and comments and matched Claude and DeepSeek against them; Claude then labels about 6,000 posts, and rules mined from its reasoning prompt DeepSeek to label about 12,000 more.
 - **Images and video.** A PyTorch fusion classifier over CLIP embeddings of image, OCR text and caption (macro-F1 0.93 on a 149-item gold set; production labels from Claude Haiku 4.5 vision); a hybrid OCR pipeline (token-F1 0.928); Whisper transcription.
 - **Evaluation design.** Release gate of macro-F1 above 0.85 on both a 97-post human holdout and a 4,000-item stratified test set, then a human check of 200 random posts; weekly KL-divergence drift alarms.
 - **Research base.** Features reviewed against the literature: Grimmer, Roberts and Stewart's *Text as Data* (hold back future data for testing, never present a prediction as a cause, check labels against human judges), published popularity-prediction benchmarks for flop detection, and the ranking code X released as open source.

Dec 2024 - present

- Data Engineer, consultant**, M+C Saatchi Fluency, United Kingdom (remote). Analysing online data (social posts, forums, reviews, search) for brands, and supporting UK Government social listening pipelines.
- **Method under challenge.** CFMOTO 2027 launch report (eight brands): eight-theme sentiment codebook and composite metrics with written formulas. With the team, I answered client challenges with source-mix audits, a consumer-base minimum for all brands, re-tagging agreement checks and consumer-only and non-US sensitivity runs; anything the checks did not support was reported as directional.
 - **Social discourse analysis.** US women's soccer: over 100,000 consumer posts filtered in Python from a year of Twitter, forum and Reddit data; accounts classified by speaker; BERTopic topics merged by hand into a codebook; every post LLM-coded for sentiment and themes, hand-checked on a 500-post pilot.
 - **Emotion and need-state analysis.** Abbott: about 170,000 multilingual posts and reviews on infant formula from 12 platforms in Asia, Latin America and the Middle East, coded in LLM-assisted stages (translation, relevance, need states, 24 emotions, themes) and compared across markets with small-cell suppression. Reckitt: over 33,000 US reviews and about 19,000 search keywords LLM-coded on one 16-need framework; a survey deep dive from respondent-level SPSS data on the filters and bases of a validated earlier deck.
 - **Social listening pipelines** on AWS for UK Government departments, Amazon, Ford and Nike. UK Government: contributed to a reporting pipeline (ingest, AI tagging, comment processing, data-quality monitoring). Amazon: Sprinklr ETL (cleaning, deduplication, translation, tagging into Postgres and Tableau). Ford: 68 collectors on owner forums and other sources across ten platforms, with a self-healing repair agent.

Feb 2022 - Aug 2024

- Senior Data Engineer**, Dubizzle Labs (Dubizzle, Bayut, Zameen, OLX), Pakistan. Promoted twice in two years.
- **Competitor analysis.** Analysed e-commerce and real estate stores and online discussions via web scraping and the data warehouse I redesigned, for dashboards predicting revenue and showing what customers say.
 - **Collection.** Led three engineers and 500+ collectors gathering text in English, Arabic, Urdu and Hindi from 15 MENA countries, where I first saw forum and social text treated as comparable.

2018 - present

Earlier and concurrent engagements

- **Fix.com**, Canada, part-time since May 2023 (50M+ data points, 200+ sources); **VendueTech**, Ireland, Lead Data Engineer, 2025; **Prefe**, Italy, 2024; **CXG**, Dubai, 2025 to 2026; **freelance**, 2018 to 2026, 300+ clients.

AWARDS, PUBLIC WORK AND LANGUAGES

Chevening	Chevening Scholar 2024/25 (UK FCDO), selected from 70,000+ applicants in 160 countries; funded the MSc.
Public work	Author of web-scraping-guide.com, a free public reference on web data collection, its ethics and data quality.
Languages	Urdu (native). English: MSc in English; IELTS Academic 6.5. No German yet; I would begin learning it on arrival.
Availability	Can start in November 2026 and relocate to Tübingen.

National University of Computer & Emerging Sciences

This is to certify that

Mr. Asad Ikram

has been admitted to the degree of

Bachelor of Science (Computer Science)

With all the honours, privileges, and responsibilities pertaining thereto.

Awarded in the city of Islamabad on the Thirty First day of January in the year 2022.

A stylized, handwritten signature in black ink, consisting of a large, looped 'A' followed by a horizontal line and a small flourish.

Rector

A handwritten signature in black ink, appearing to read 'Wasim Sajjad' with a horizontal line underneath.

Chancellor
